Linear Regression

Formulas

$$\begin{split} y &= X\beta + \epsilon, \epsilon \sim \mathcal{N}(0, \sigma^2 \mathbb{I}) \\ \hat{\beta} &= (X^T X)^{-1} X^T y \\ P &= X (X^T X)^{-1} X^T \\ \hat{\beta} &\sim \mathcal{N}(\beta, \sigma^2 (X^T X)^{-1}) \\ \hat{y} &\sim \mathcal{N}(X\beta, \sigma^2 P) \\ e &= y - \hat{y} \sim \mathcal{N}(0, \sigma^2 (\mathbb{I} - P)) \\ \hat{\sigma}^2 &= \frac{1}{n-p} \sum_{i=1}^n (y_i - x_i^T \hat{\beta})^2 \\ \hat{\sigma}^2 &\sim \frac{\sigma^2}{n-p} \mathcal{X}_{n-p}^2 \end{split}$$

Adjusted R score

$$TSS = \sum_{i=1}^{n} (y_i - y_{mean})^2, \ RSS = \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

$$\frac{1}{n-1}TSS = \text{sample variance of } y_1, ..., y_n$$

$$\frac{1}{n-1}RSS = \text{sample variance of } e_1, ..., e_n$$

$$R^2 = 1 - \frac{RSS}{TSS}$$

$$R^2 = 0 \text{ means model do nothing}$$

$$R^2 = 1 \text{ model completely fits}$$

$$R_{adj}^2 = 1 - \frac{RSS/(n-p)}{TSS/(n-1)}$$

$$F = \frac{(RSS_1 - RSS_2)/(p_2 - p_1)}{RSS_2/(n-p_2)}$$

Std Errors and P values of beta

$$\begin{split} Se(\hat{\beta}_k) &= \sqrt{\hat{\sigma}^2[(X^TX)^{-1}]_{kk}}\\ &\frac{\hat{\beta}_j - 0}{\sqrt{\hat{\sigma}^2[(X^TX)^{-1}]_{kk}}} \sim t_{n-p} \text{ under null} \end{split}$$

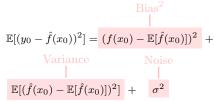

Type 1 and 2 errors

		True State of Nature	
		H_0 true	H_0 false
Decision	Accept H_0 Reject H_0	Correct Probability = $(1 - \alpha)$ Wrong (type I error) Level of significance = α	Wrong (type II error) Probability = β Correct Power = $1 - \beta$

Confidence Intervals

$$\begin{split} &(1-\alpha)100\% \text{ confidence interval for } \mathbb{E}[y_0] = x_0^T\beta: \\ &x_0^T\hat{\beta} \pm \hat{\sigma}\sqrt{x_0^T(X^TX)^{-1}x_0} \ t_{1-\frac{\alpha}{2},n-p} \\ &(1-\alpha)100\% \text{ confidence interval for } y_0: \\ &x_0^T\hat{\beta} \pm \hat{\sigma}\sqrt{1+x_0^T(X^TX)^{-1}x_0} \ t_{1-\frac{\alpha}{2},n-p} \end{split}$$

Bias Variance Decomposition

Bootstrap

Consistency with convergence rate α_n for $\hat{\theta}_n$:

not random-
want to approx via
know bootstrap
$$\mathbb{P}[\alpha_n(\hat{\theta}_n - \theta)] - \mathbb{P}^*[\alpha_n(\hat{\theta}_n^* - \hat{\theta}_n)]$$
$$\frac{P}{\rightarrow} 0 \text{ as } n \rightarrow \infty$$

Consistency holds if $\alpha_n(\hat{\theta}_n - \theta) \sim \mathcal{N}(\theta, \sigma^2)$ Bias and Variance estimation for $\hat{\theta}_n$:

$$bias(\hat{\theta}_n) \approx \mathbb{E}^*[\hat{\theta}_n^*] - \hat{\theta}_n \approx \hat{\beta}_n^* - \hat{\theta}_n$$
$$var(\hat{\theta}_n) \approx var(\hat{\theta}_n^*) \approx \frac{1}{B-1} \sum_{i=1}^{B} (\hat{\theta}_n^{*b} - \hat{\beta}_n^*)^2$$

Bootstrap CIs:

- quantile(**percentile**): $[q_{\hat{\theta}^*}(\frac{\alpha}{2}), q_{\hat{\theta}^*}(1-\frac{\alpha}{2})]$
- normal(normal): $\hat{\theta}_n \pm q_Z(1 \frac{\alpha}{2})\hat{sd}(\hat{\theta}_n)$ where $Z \sim \mathcal{N}(0,1)$, $\hat{sd}(\hat{\theta}_n) = \sqrt{\hat{var}^*(\hat{\theta}_n^*)}$ R uses $\hat{\theta}_n - \hat{bias}$ as midpoint
- reversed quantile(basic):

$$[\hat{\theta}_n - q_{\hat{\theta}_n^* - \hat{\theta}_n}(1 - \frac{\alpha}{2}), \hat{\theta}_n - q_{\hat{\theta}_n^* - \hat{\theta}_n}(\frac{\alpha}{2})]$$

• Bootstrap T(stud): $[\hat{\theta}_n - q_{\hat{\theta}_n^* - \hat{\theta}_n} (1 - \frac{\alpha}{s}) \hat{sd}(\hat{\theta}_n^*), \hat{\theta}_n - q_{\hat{\theta}_n^* - \hat{\theta}_n} (\frac{\alpha}{2}) \hat{sd}(\hat{\theta}_n^*)]$

Wilcoxon signed rank test

permute signes and use this statistic: $V = \sum_{i} rank(|D_i|).\mathbb{1}_{D_i>0}$

Multiple Testing

		True State of Nature		
		H ₀ true	H_0 false	Total
Decision	H_0 is not rejected	U	T	m - R
	H_0 is rejected	V	S	R
	Total	m_0	$m-m_0$	m

- $FDP : Q = \frac{V}{R}, FDR := \mathbb{E}[Q]$
- $-FWER := \mathbb{P}(V \ge 1)$ global null : $m = m_0$
- -FWER = FDR under the global null
- -FWER > FDR in general
- if $m_0 \ge 1$ and the tests are exactly at level $\alpha \Rightarrow FWER \ge \alpha$
- $-FWER \le \alpha m$
- FWER Control Bonferroni: conduct m tests at level $\frac{\alpha}{m}$

- under global null, with all tests at level α , $FWER = 1 (1 \alpha)^m$ and with first order tylor: $FWER \approx m\alpha$
- in case of dependant tests (We want distribution of min(pvalues) under the global null): conduct FWER Control-Westfall Young and find $\sigma := \alpha$ quantile of $minp_j$ with permutation test under the global null and conduct all tests at level σ . For a dataset with n points and m variables: shuffle y column, compute p-value for each m variables (e.g Wilcoxon) store $min(p_1, ..., p_m)$ repeat.
- FDR Control Benjamini Hochberg: want to have FDR rate q? order p-values and find the largest i such that $p_{(i)} \leq \frac{i}{m}q$ reject null hyp. for all tests j, $j \leq i$ (Only works for independant p-values)

Beyond Linearity

- Orthogonal Basis: when adding new orthogonal basis to a function: estimates for other coef will be the same, p-values will change. Anova will use the p-values of the largest model.
- Number of free parameters in **cubic** spline with k knots? k+1 intervals with 4 parameters $\Rightarrow 4(k+1)$ parameters. k knots with 3 constraints per knot: 3(k) to be reduced. So in total 4(k+1) 3k = k+4 parameters. (In
- Number of free parameters in **natural cubic spline** with k knots(same as cubic spline but linear outside of knots)? k + 4 2 * 2 = k (In R use k + 1)

R reduce one to omit intercept k+3)

- Good Basis function for cubic spline? $\beta_0 + \beta_1 x_i + \beta_2 x_i^2 + \beta_3 x_i^3 + \gamma_1 (x c_1)_+^3 + \gamma_2 (x c_2)_+^3 + \dots + \gamma_k (x c_k)_+^3$
- Smoothing Spline $\hat{g} = \underset{g \in G}{argmin} \{ \sum (y_i g(x_i))^2 + \lambda \int_a^b g''(x)^2 dx \}$ if $\lambda = 0$ interpolate all points(**n** degress of freedom), if $\lambda = \infty$ LS solution(2 degrees of

freedom). In general equivalent to

shrunken version of natural cubic

- Backfitting Algorithm

spline.

repeat for each predictor j do $\hat{g}_j \leftarrow S_j(y - \hat{\mu} - \sum_{k \neq \hat{g}_k})$ $\hat{g}_j \leftarrow \hat{g}_j - mean(\hat{g}_j)$ where $mean(\hat{g}_j) = \frac{1}{n} \sum_i \hat{g}_j(X_{ij})$

end for until Convergence
